## Hydrogen Bond Directed Self-Assembly of $\pi$ -Systems from Solution to Optoelectronic Thin Films

Prof. Dr. Ronald K. Castellano

Department of Chemistry, University of Florida

日時：8月3日（金）  
15:00 ~ 17:00  
場所：R1棟 第1会議室  
連絡先：福島 孝典 (5220)

### ABSTRACT and REFERENCES

Although “ordered” organic  $\pi$ -conjugated assemblies outperform “disordered” ones in many optoelectronic device applications, we are far from being able to port the well-understood supramolecular recipes of  $\pi$ -systems from solution to solid-state device environments. For the past several years we have been exploring hydrogen bond (H-bond) directed self-assembly of  $\pi$ -systems along these lines, for example, to enhance their absorption and charge transport properties for organic photovoltaic (OPV) applications.<sup>1</sup> Various examples of oligothiophenes outfitted with heterocycles capable of forming H-bonded “rosettes” will be discussed in this context. The second part of the talk will introduce new monomers derived from [2.2]paracyclophane (pCp) that are capable of robust H-bond directed self-assembly into one-dimensional nanostructures in solution and the solid state.<sup>2</sup> The design introduces transannular (intramolecular) H-bonds between pairs of pseudo-ortho-positioned amides as a way to preorganize the molecules for intermolecular H-bonding with two neighbors. The result is formation of homochiral, one-dimensional pCp stacks that show supramolecular polymer signatures in solution.
